refitME: Tutorial for fitting measurement error models using Monte Carlo Expectation Maximization in R

Jakub Stoklosa, Hwang W-H., & David Warton

04 December, 2020

This tutorial documents fitting an MCEM algorithm via the refitME R-package. For more specific details see: refitME: Measurement Error Modelling using Monte Carlo Expectation Maximization in R. Also, see ?refitME for further details on the fitting function, input arguments and output.

Example 1: A simple GLM example taken from Carroll et al. (2006).

We use the Framingham heart study data set. In addition to the naive model, we also fit a simex model and compare it with MCEM. Computational times for both models are also reported.

Load data and R-packages.

```
suppressWarnings(suppressMessages(library(refitME)))
suppressWarnings(suppressMessages(library(simex)))
set.seed(2020)
B <- 100 # The number of Monte Carlo replication values/SIMEX simulations.
data(Framinghamdata)</pre>
```

Setup all variables (the construction below follows the Carroll et al. (2006) monograph).

```
W <- as.matrix(Framinghamdata$w1) # Matrix of error-contaminated covariate.
sigma.sq.u <- 0.01259/2 # ME variance, obtained from Carroll et al. (2006) monograph.
```

Fit the naive model.

The first stored variable w1 is the error contaminated variable used in the analysis.

Fit the SIMEX model.

Fit the MCEM model.

```
start <- Sys.time()
glm_MCEM1 <- refitME(glm_naiv1, sigma.sq.u, W, B)

## [1] "One specified error-contaminated covariate."
## [1] "convergence :-)"
## [1] 5

end <- Sys.time()
t2 <- difftime(end, start, units = "secs")
comp.time <- c(comp.time, t2)</pre>
```

Report model estimates and compare computational times.

```
est.beta <- rbind(coef(glm_naiv1), coef(glm_simex1), coef(glm_MCEM1))</pre>
est.beta.se <- rbind(sqrt(diag(vcov(glm_naiv1))),</pre>
                  sqrt(diag(glm_simex1$variance.jackknife)), sqrt(diag(vcov(glm_MCEM1))))
row.names(est.beta) = row.names(est.beta.se) <- c("Naive GLM", "SIMEX", "MCEM")</pre>
colnames(est.beta) = colnames(est.beta.se) <- c("(Intercept)", "SBP", "chol. level",</pre>
                                              "age", "smoke")
round(est.beta, digits = 3)
            (Intercept) SBP chol. level
                                           age smoke
               -14.951 1.707
## Naive GLM
                              0.008 0.055 0.592
## SIMEX
                -15.919 1.947
                                   0.008 0.053 0.598
## MCEM
               -16.059 1.955 0.008 0.056 0.594
round(est.beta.se, digits = 3) # Standard error estimates.
            (Intercept) SBP chol. level
                                           age smoke
## Naive GLM
                2.043 0.456
                                  0.002 0.012 0.251
## SIMEX
## MCEM
                 2.185 0.487
                                   0.002 0.012 0.250
```

```
names(comp.time) <- c("SIMEX", "MCEM")
comp.time # SIMEX and MCEM.

## Time differences in secs
## SIMEX MCEM
## 10.033162 4.911769</pre>
```

Example 2: A GAM example taken from Ganguli et al. (2005).

The Milan mortality air pollution data set. Here, we fit GAM models via the mgcv package where one covariate is error-contaminated.

Load data and R-packages.

```
suppressWarnings(suppressMessages(library(refitME)))
set.seed(2020)
epsilon <- 0.00001 # A set convergence threshold.

B <- 50 # The number of Monte Carlo replication values.
data(milan.mort)
dat.air <- milan.mort</pre>
```

Setup all variables.

```
Y <- dat.air[, 6]  # Mortality counts.
n <- length(Y)

z1 <- (dat.air[, 1])
z2 <- (dat.air[, 4])
z3 <- (dat.air[, 5])
w1 <- log(dat.air[, 9])
W <- as.matrix(w1)
dat <- data.frame(cbind(Y, z1, z2, z3, w1))

sigma.sq.u <- 0.0915  # This gives a reliability ratio of 0.7.
rel.rat <- round((1 - sigma.sq.u/var(dat$w1))*100, digits = 0)</pre>
```

Fit the naive model.

```
gam_naiv1 \leftarrow gam(Y \sim s(w1) + s(z1, k = 25) + s(z2) + s(z3), family = "poisson", data = dat)
```

Fit the MCEM model.

Note this will take a fair while to run if B is large (consider decreasing B if you want a rough answer).

```
gam_MCEM1 <- refitME(gam_naiv1, sigma.sq.u, W, B)

## [1] "One specified error-contaminated covariate."
## [1] "convergence :-)"
## [1] 14</pre>
```

MCEM (Poisson GAM) fitted to the air pollution data.

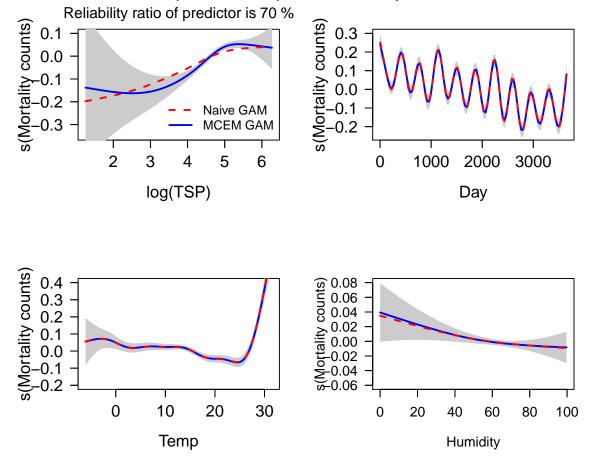

Figure 1: Plots of smooths against covariate. TSP (top left is the error contaminated variable).

Example 3: A point-process model using presence-only data

We use the *Corymbia eximia* presence-only data set from Renner and Warton (2013). Here, we fit a naive models point-process model (PPM) and an MCEM PPM.

Load data and R-packages.

```
suppressWarnings(suppressMessages(library(refitME)))
data(Corymbiaeximiadata)
suppressMessages(attach(Corymbiaeximiadata))
```

Setup all variables.

Fit the naive (PPM) model.

```
PPM_naiv1 <- glm(Y/p.wt ~ X1 + X2 + Z1 + Z2 + Z3 + Z4, family = "poisson",
weights = p.wt, data = dat)</pre>
```

Fit the MCEM PPM.

```
B <- 50
sigma.sq.u <- 0.25

PPM_MCEM1 <- refitME(PPM_naiv1, sigma.sq.u, W, B)

## [1] "One specified error-contaminated covariate."
## [1] "convergence :-)"
## [1] 5</pre>
```

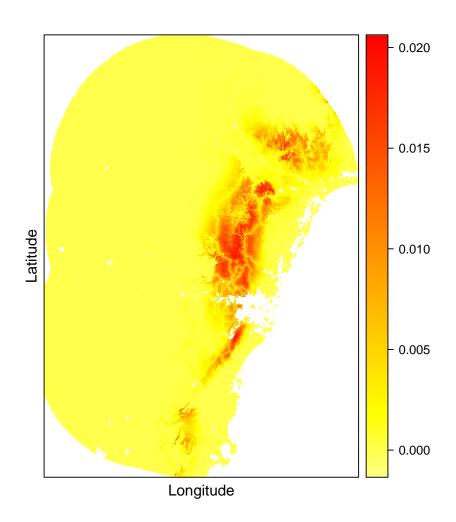

Figure 2: Plot of predicted presences of Corymbia eximia using presence-only data when fitting the MCEM model. Here the max temperature covariate is assumed to be error-contaminated.
